Django tutorial Part 1 (Windows)

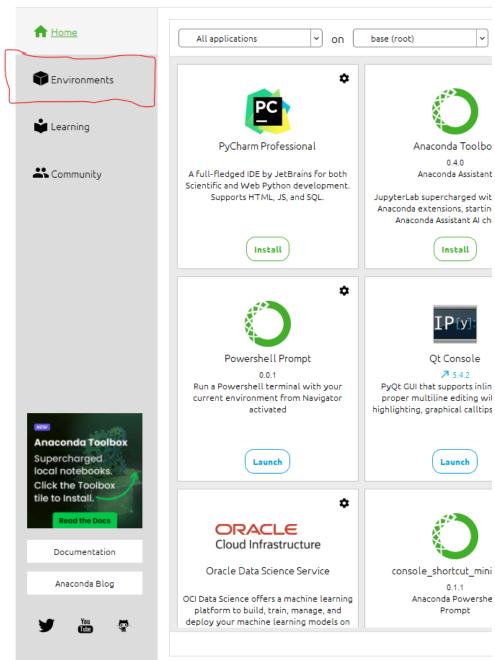

Getting started with Django | Django (djangoproject.com)

- 1. Install Anaconda Navigator
- 2. Open it and navigate to environments

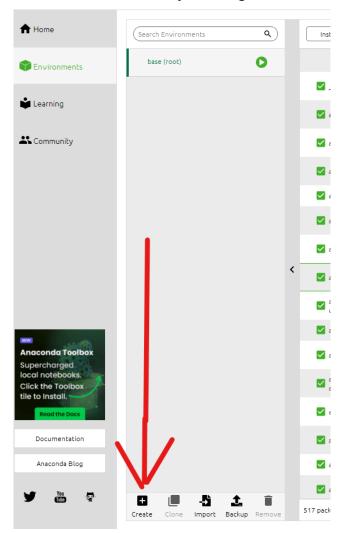

Anaconda Navigator

<u>F</u>ile <u>H</u>elp

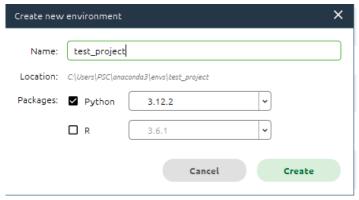

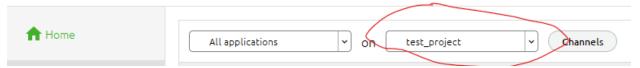

3. This is where we'll be creating a virtual environment that Django will use. Create a new environment by clicking 'Create'

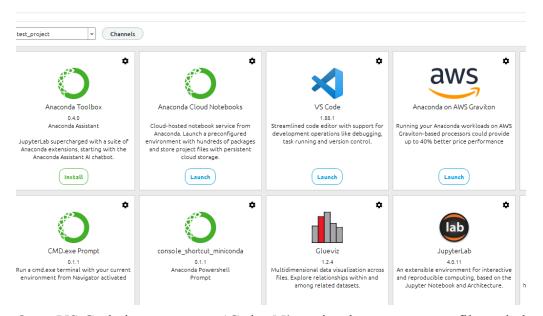

4. Name the environment 'test_project', tick the python package and select the latest version of Python available. Then click 'Create'.

5. Once it's finished loading, go back to the home page and make sure it's on 'test project'

6. Find VS Code and click 'launch'.

7. Once VS Code is open, press 'Ctrl + N' or simply create a new file and change the programming language at the bottom right to Python. (Click on 'Plain Text' and type 'Python', then click on it) If you can't find Python then you'll need to install the Python extension in VS Code.

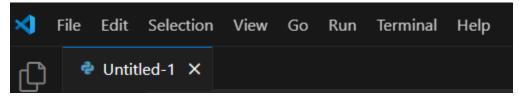

8. Doing so should display this,

which shows that you're currently working in the virtual environment. (Although VS Code can create virtual environments, using Anaconda to create one allows you to change the Python version to suit your needs if necessary.)

9. Start by opening a new terminal (top left corner).

10. Once it's open, enter 'py -m pip install –upgrade pip' and run it.

```
PROBLEMS OUTPUT DEBUG CONSOLE <u>TERMINAL</u> PORTS

PS C:\Users\PSC> py -m pip install --upgrade pip
```

11. Once it's done updating, we'll now start to install Django. While you're in the terminal, type 'py -m pip install Django' and run it. Ensure the spelling and capitalisation are all correct.

```
PS C:\Users\PSC> py -m pip install Django
```

12. After Django is done installing, we can check to make sure it's installed by running 'py -m django –version' in the terminal.

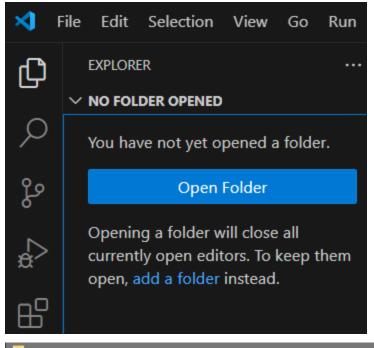

```
PS C:\Users\PSC> py -m django --version 5.0.4
PS C:\Users\PSC>
```

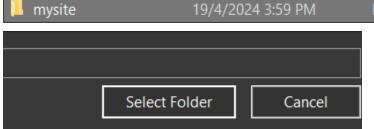

If Django is installed, a version number will appear. For this tutorial Django needs to be at least version 5.0 or above.

13. To create our Django project, run 'django-admin startproject mysite' in the terminal. Doing this will tell Django to create a project named 'mysite', the name can be modified if you wish.

```
PS C:\Users\PSC> django-admin startproject mysite
```

14. To make navigating through our different files easier, we'll need to create a workspace in VS Code. Click on explorer and click on 'Open Folder'. Now find the file that contains your Django project and select it.

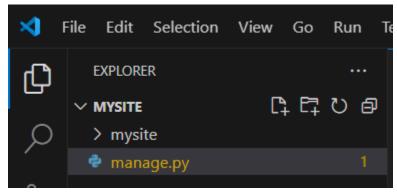

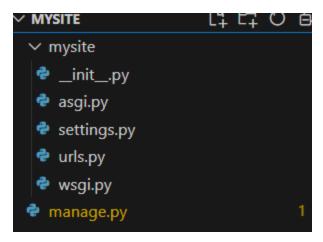

15. Alternatively, if you want to store your project elsewhere, simply type 'cd' and add a space, followed by the file path of your destination of choice.

```
PS C:\Users\PSC\mysite> cd C:\Users\PSC
PS C:\Users\PSC>
```

16. Upon doing so, you should see a directory towards the left which allows us to access our project's different files and folders more easily.

17. Now, let's take a look at the files that came with our project:

- manage.py: This file is a command-line utility that allows you to interact with the project in numerous ways including checking what changes have been made to your project or running your website.
- __init__.py: This file tells Python that the inner 'mysite' file should be considered a Python package.
- settings.py: This file acts as the settings/configuration for your project and can be modified.
- urls.py: This file contains the URLs that your project will use, it can also be reused in other projects.
- asgi.py: This file acts as an entry point for ASGI-compatible web servers to host your project.
- wegi.py: This file acts as an entry point for ASGI-compatible web servers to host your project.
- 18. Try running 'py manage.py runserver' in your VS Code terminal, you should then see something like this:

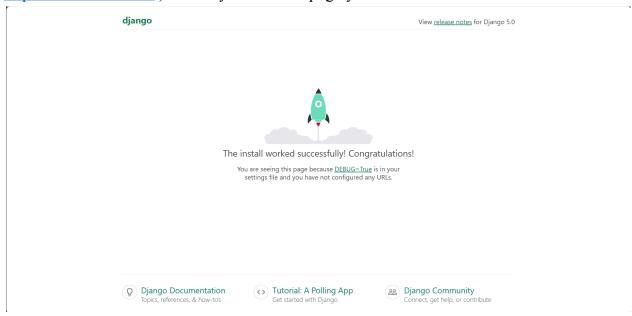

```
PS C:\Users\PSC\mysite> py manage.py runserver
Watching for file changes with StatReloader
Performing system checks...

System check identified no issues (0 silenced).

You have 18 unapplied migration(s). Your project may not work properly until you apply the migrations for app(s): admin, auth, contenttypes, sessions.
Run 'python manage.py migrate' to apply them.

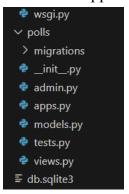

April 22, 2024 - 09:43:47
Django version 5.0.4, using settings 'mysite.settings'
Starting development server at http://127.0.0.1:8000/
Quit the server with CTRL-BREAK.
```

Once this is done, you can visit the link shown in your terminal (in this case it's http://127.0.0.1:8000/). When you visit the page you should see this:

If you see this, it means that your Django server deployed successfully.

- 19. Now, stop the server by pressing 'CTRL + C' at the same time while in the terminal.
- 20. By default, Django launches its server with a port number of 8000, this can be changed. To do so, type 'py manage.py runserver' but don't run it just yet. After 'runserver', add any 4 digit number and then run the code, it should look something like 'py manage.py runserver 9000'.
- 21. Now, we'll be creating our 'polls' app. Ensure your terminal is in the same directory as 'manage.py' and run 'py manage.py startapp polls'. This should then appear:

22. Open 'views.py' in the polls folder and type the following code(always save the file you're working on after making any changes):

```
views.py X

1  from django.http import HttpResponse
2
3  def index(request):
4  return HttpResponse("Hello, world. You're at the polls index.")
```

- 23. This is what your server should look like:
 You may have noticed that nothing has changed, this is because even though we just created a view, we still haven't told our project to navigate and find this view.
- 24. To fix this, create a python file named 'urls.py' in the polls folder (for future reference when opening files, we'll be using 'folder name'/'file name'; for example 'polls/urls.py', which is what we've opened here) and type the following code:

```
from django.urls import path

from . import views

urlpatterns = [
path("", views.index, name="index"),

path("", views.index, name="index"),
```

25. Now, we'll be instructing our project to navigate through specific directories so that we can see for ourselves what our view actually looks like. To do so, open 'mysite/urls.py' and type in the following code (you can just leave the orange text above alone):

```
2. Add a ORL to dispatterns: path( blog/
"""

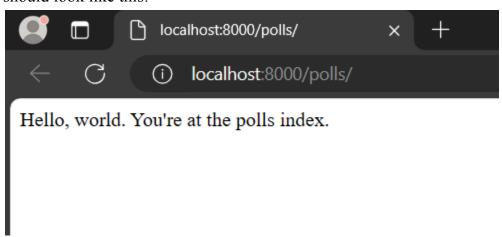

from django.contrib import admin
from django.urls import include, path

urlpatterns = [

path("polls/", include("polls.urls")),
path("admin/", admin.site.urls),

]
```

26. The 'include' function in Django allows the project to reference other URLS. Whenever Django sees 'include()', it removes whatever part of the URL leading up to a certain point and sends the rest through, which makes it easy to 'plug and play' numerous URLs. Now run 'py manage.py runserver' and visit http://localhost:8000/polls/ or http://localhost:8000/, if the first link doesn't work. If you've used a different port number for your server, make sure to make that change in the link when opening it. Note that you'll encounter a 'Page not found' (error 404) if you try visiting the link given in your VS Code terminal. Your page should look like this:

Django tutorial Part 2

1. By default, Django uses SQLite as its database since it comes pre-installed with Python. In the future, you may want to switch to a more scalable database like PostgreSQL to avoid database-switching headaches down the road. Now, open 'mysite/settings.py' and scroll down until line 33 where you can see the 'INSTALLED APPS':

```
33   INSTALLED_APPS = [
34     "django.contrib.admin",
35     "django.contrib.auth",
36     "django.contrib.contenttypes",
37     "django.contrib.sessions",
38     "django.contrib.messages",
39     "django.contrib.staticfiles",
40 ]
```

- 2. We'll go through briefly what each of these apps do:
 - django.contrib.admin: The admin site. We'll be using it soon

- django.contrib.auth: An authentication system
- django.contrib.contenttypes: A framework for different content types
- django.contrib.sessions: A session framework
- django.contrib.messages: A messaging framework
- django.contrib.staticfiles: A framework for managing static files
- 3. Run 'py manage.py migrate' in the VS Code terminal, you should see something like this:

```
PS C:\Users\PSC\mysite> py manage.py migrate
Operations to perform:
  Apply all migrations: admin, auth, contenttypes, sessions
Running migrations:
  Applying contenttypes.0001 initial... OK
  Applying auth.0001 initial... OK
  Applying admin.0001 initial... OK
  Applying admin.0002 logentry remove auto add... OK
  Applying admin.0003 logentry add action flag choices... OK
  Applying contenttypes.0002 remove content type name... OK
  Applying auth.0002 alter permission name max length... OK
  Applying auth.0003 alter user email max length... OK
  Applying auth.0004 alter user username opts... OK
  Applying auth.0005 alter user last login null... OK
  Applying auth.0006 require contenttypes 0002... OK
  Applying auth.0007 alter validators add error messages... OK
  Applying auth.0008 alter user username max length... OK
  Applying auth.0009 alter user last name_max_length... OK
  Applying auth.0010 alter group name max length... OK
  Applying auth.0011 update proxy permissions... OK
  Applying auth.0012 alter user first name max length... OK
  Applying sessions.0001 initial... OK
PS C:\Users\PSC\mysite>
```

4. In our polls app, we'll be creating 2 models: 'Question' and 'Choice'. 'Question' has a question and publication date while 'Choice' has 2 fields, a text of choice and a vote tally. Each choice will be associated with a question. Open

'polls/models.py' and type the following code:

- 5. Here, each model (Question and Choice) are represented by subclasses (models.Model). Each model has a number of class variables, each of which represents a database field in the model. Each field is then represented by an instance of a 'Field' class, e.g. 'CharField' for character fields and 'DateTimeField' for datetimes. A relationship is then defined between the 2 models using 'ForeignKey', which tells Django that each 'Choice' is related to a single 'Question'.
- 6. We now need to inform our project that the 'polls' app is installed. To do this, open 'mysite/settings.py' and edit the 'INSTALLED_APPS' section by adding "polls.apps.PollsConfig" in there and add a comma at the end (the comma is very important). It should now look something like this:

```
INSTALLED_APPS = []

Impolls.apps.PollsConfig",

"django.contrib.admin",

"django.contrib.auth",

"django.contrib.contenttypes",

"django.contrib.sessions",

"django.contrib.messages",

"django.contrib.staticfiles",

"django.contrib.staticfiles",

"django.contrib.staticfiles",
```

7. Run 'py manage.py makemigrations polls' in the VS Code terminal and you should see this:

```
PS C:\Users\PSC\mysite> py manage.py makemigrations polls

Migrations for 'polls':

polls\migrations\0001_initial.py

- Create model Question

- Create model Choice

PS C:\Users\PSC\mysite>
```

By running 'makemigrations', we're telling Django that we've made some changes to our models (or made new ones) and that you'd like these changes to be stored as a migration. Migrations are how Django stores changes to your models, they're files on disk.

8. Run 'py manage.py sqlmigrate polls 0001' in your terminal and you should see something like this (note that the exact output may vary depending on what database you're using):

```
PS C:\Users\PSC\mysite> py manage.py sqlmigrate polls 0001
BEGIN;
--
-- Create model Question
--
CREATE TABLE "polls_question" ("id" integer NOT NULL PRIMARY KEY AUTOINCREMENT, "question_text" varchar(200) NOT NUL
--
-- Create model Choice
--
CREATE TABLE "polls_choice" ("id" integer NOT NULL PRIMARY KEY AUTOINCREMENT, "choice_text" varchar(200) NOT NULL, 'NCES "polls_question" ("id") DEFERRABLE INITIALLY DEFERRED);
CREATE INDEX "polls_choice_question_id_c5b4b260" ON "polls_choice" ("question_id");
COMMIT;
```

- 9. The 'sqlmigrate' command doesn't actually make the migration happen, instead, it shows you what SQL Django thinks is needed. Now run 'py manage.py migrate' in the terminal. The 'migrate' command checks all the unapplied migrations, runs them against your database and synchronises the changes you made to the models with schema in your database. Migrations are very powerful since they allow you to change your models over time without the need to delete your databases/tables or make new ones it specialises in upgrading your database live, without losing any data. To make future changes to your models, remember this three step process:
 - 1. Change your models in 'models.py'
 - 2. Run 'py manage.py make migrations' to create migrations for those changes
 - 3. Run 'py manage.py migrate' to apply those changes to the database

10. Run 'py manage.py shell' in your terminal to invoke the Python shell and type in the following commands as shown (the non-highlighted text in the picture consist of informative notes or output from the terminal, so only type the highlighted text):

```
>>> from polls.models import Choice, Question # Import the model classes we just wrote.
# No questions are in the system yet.
>>> Question.objects.all()
<QuerySet []>
# Create a new Question.
# Django expects a datetime with tzinfo for pub_date. Use timezone.now()
# instead of datetime.datetime.now() and it will do the right thing.
>>> from django.utils import timezone
>>> q = Question(question_text="What's new?", pub_date=timezone.now())
>>> q.save()
>>> q.id
>>> q.question_text
>>> q.pub_date
datetime.datetime(2012, 2, 26, 13, 0, 0, 775217, tzinfo=datetime.timezone.utc)
# Change values by changing the attributes, then calling save().
>>> q.question_text = "What's up?"
>>> q.save()
# objects.all() displays all the questions in the database.
>>> Question.objects.all()
```

11. To exit the Python shell simply type 'exit()' or press 'CTRL + Z' and enter. Open 'polls/models.py' and add this code to it:

```
class Question(models.Model):
    # ...
    def __str__(self):
        return self.question_text

class Choice(models.Model):
    # ...
    def __str__(self):
        return self.choice_text
```

The '# ...' section tells us that we should leave the above section alone. Your code should now look like this:

```
from django.db import models

class Question(models.Model):
    question_text = models.CharField(max_length=200)
    pub_date = models.DateTimeField("date published")
    def __str__(self):
        return self.question_text

class Choice(models.Model):
    question = models.ForeignKey(Question, on_delete=models.CASCADE)
    choice_text = models.CharField(max_length=200)
    votes = models.IntegerField(default=0)
    def __str__(self):
    return self.choice_text
```

12. The '__str__()' method makes it more convenient when using the Python shell. Now edit 'polls/models.py' with the following:

```
polls/models.py ¶

import datetime

from django.db import models
from django.utils import timezone

class Question(models.Model):
    # ...
    def was_published_recently(self):
        return self.pub_date >= timezone.now() - datetime.timedelta(days=1)
```

Your code should now look like this:

```
import datetime

from django.db import models
from django.utils import timezone

class Question(models.Model):
    question_text = models.CharField(max_length=200)
    pub_date = models.DateTimeField("date published")
    def __str__(self):
        return self.question_text
    def was_published_recently(self):
        return self.pub_date >= timezone.now() - datetime.timedelta(days=1)

import datetime

from django.db import models

from django.db import timezone

from django.db import timezone

from django.db import models

from django.db import timezone

from django.db import models

from django.db import timezone

from django.db impor
```

The 'class Choice(models.Model)' section was left out because no changes were made to it.

13. The addition of 'import datetime' allows us to use Python's standard 'datetime' module while 'django.utils import timezone' allows us to use Django's time-zone-related utilities. Now open the Python shell by running 'py manage.py shell' in your terminal again and type in the following commands (there are multiple pictures):

```
>>> from polls.models import Choice, Question
# Make sure our <u>str</u> () addition worked.
>>> Question.objects.all()
<QuerySet [<Question: What's up?>]>
# Django provides a rich database lookup API that's entirely driven by
# keyword arguments.
>>> Question.objects.filter(id=1)
<QuerySet [<Question: What's up?>]>
>>> Question.objects.filter(question_text__startswith="What")
<QuerySet [<Question: What's up?>]>
# Get the question that was published this year.
>>> from django.utils import timezone
>>> current year = timezone.now().year
>>> Question.objects.get(pub_date__year=current_year)
<Question: What's up?>
# Request an ID that doesn't exist, this will raise an exception.
>>> Question.objects.get(id=2)
Traceback (most recent call last):
DoesNotExist: Question matching query does not exist.
# Lookup by a primary key is the most common case, so Django provides a
# shortcut for primary-key exact lookups.
# The following is identical to Question.objects.get(id=1).
>>> Question.objects.get(pk=1)
<Question: What's up?>
```

```
# Make sure our custom method worked.
>>> q = Question.objects.get(pk=1)
>>> q.was published recently()
# Give the Question a couple of Choices. The create call constructs a new
# Choice object, does the INSERT statement, adds the choice to the set
# of available choices and returns the new Choice object. Django creates
# a set (defined as "choice set") to hold the "other side" of a ForeignKey
# relation (e.g. a question's choice) which can be accessed via the API.
>>> q = Question.objects.get(pk=1)
# Display any choices from the related object set -- none so far.
>>> q.choice set.all()
<QuerySet []>
# Create three choices.
>>> q.choice_set.create(choice_text="Not much", votes=0)
<Choice: Not much>
>>> q.choice_set.create(choice_text="The sky", votes=0)
<Choice: The sky>
>>> c = q.choice set.create(choice text="Just hacking again", votes=0)
# Choice objects have API access to their related Question objects.
>>> c.question
<Question: What's up?>
# And vice versa: Question objects get access to Choice objects.
>>> g.choice set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
>>> q.choice_set.count()
# The API automatically follows relationships as far as you need.
# Use double underscores to separate relationships.
# This works as many levels deep as you want; there's no limit.
# Find all Choices for any question whose pub date is in this year
# (reusing the 'current year' variable we created above).
>>> Choice.objects.filter(question_pub_date_year=current_year)
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
# Let's delete one of the choices. Use delete() for that.
>>> c = q.choice_set.filter(choice_text__startswith="Just hacking")
>>> c.delete()
```

14. What we've done is essentially create several choices to choose from as well as learn how to filter between the different choices. Now, we'll be creating an admin user for our server. Run 'py manage.py createsuperuser' in the terminal. Once you've done this, you'll need to enter a username, your email, and a password (you'll need to type your password twice to confirm it):

```
Username (leave blank to use 'psc'): admin
Email address: admin@gmail.com
Password:
Password (again):
The password is too similar to the username.
This password is too short. It must contain at least 8 characters.
This password is too common.
Bypass password validation and create user anyway? [y/N]: y
Superuser created successfully.
PS C:\Users\PSC\mysite>
```

15. Start the server by running 'py manage.py runserver' in the terminal and then visit http://127.0.0.1:8000/admin/ (change the port number accordingly if you've used a different one):

	Django administration	
Username:		
Password:		
	Log in	

16. Enter your username and password to reach this screen:

17. The 'AUTHENTICATION AND AUTHORIZATION' section is provided by 'django.contrib.auth' in the 'INSTALLED_APPS' section of 'mysite/setting.py'. However, our polls app is seemingly missing. To remedy this, open 'polls/admin.py' and edit the code such that it looks like this:

```
from django.contrib import admin

from .models import Question

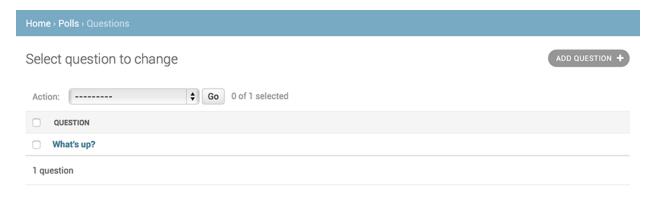

admin.site.register(Question)
```

18. Once you've saved the changes, reload your page and you should find this:

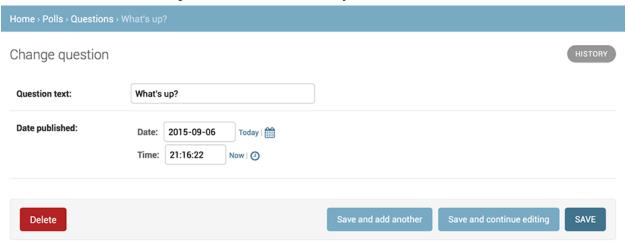

Site administration

19. Click on 'Questions' to reach this page:

20. Click on 'What's up?' and edit it however you like:

- 21. The form you see here was generated from the 'Question' model and the different field types ('DateTimeField' and 'CharField') each have their own unique HTML input widget. The 'Today' and 'Now' shortcuts that you see beside 'Date' and 'Time' are Javascript shortcuts.
- 22. If you made any changes and saved them, you can view said changes by clicking on the question and navigating to 'HISTORY' in the top right corner which'll show you this:
